Running Title: Characterization of MRFAP1

Keywords: MRFAP1, MORF4L1, MRG15, NEDD8, Cullin, MLN4924, Protein Degradation, Proteomics, Interactions.

1

Abbreviations

CUL4B	Cullin-4b
DMEM	Dulbecco's modified eagle medium
DNA	Deoxyribonucleic acid
EGFP	Enhanced green fluorescent protein
HRP	Horse radish peroxidase
MORF4	Mortality factor 4
MORF4L1	Mortality factor 4-like protein 1
MRFAP1	MORF4 family-associated protein 1
MRGBP	MRG-domain binding protein
mRNA	Messenger RNA
NEDD8	Neural precursor cell expressed developmentally down-regulated protein 8
NuA4	Nucleosome acetyltransferase of histone H4
RNA	Ribonucleic Acid
RT	Room temperature
SILAC	Stable isotope labeling with amino acids in cell culture
TBST	TBS Tween 20
TCEP	Triscarboxyethylphosphine
WT	Wildtype

Summary

The NEDD8-Cullin E3 Ligase pathway plays an important role in protein homeostasis, in particular the degradation of cell cycle regulators and transcriptional control networks. To characterize NEDD8-cullin target proteins, we performed a quantitative proteomic analysis of cells treated with MLN4924, a small molecule inhibitor of the NEDD8 conjugation pathway. MRFAP1 and its interaction partner MORF4L1 were amongst the most up-regulated proteins after NEDD8 inhibition in multiple human cell lines. We show that MRFAP1 has a fast turnover rate in the absence of MLN4924 and is degraded via the ubiquitin-proteasome system. The increased abundance of MRFAP1 after MLN4924 treatment results from a decreased rate of degradation. Characterization of the binding partners of both MRFAP1 and MORF4L1 revealed a complex protein-protein interaction network. MRFAP1 bound to a number of E3 ubiquitin ligases, including CUL4B, but not to components of the NuA4 complex, including MRGBP, which bound to MORF4L1. These data indicate MRFAP1 may regulate the ability for MORF4L1 to interact with chromatin modifying enzymes by binding to MORF4L1 in a mutually exclusive manner with MRGBP. Analysis of MRFAP1 expression in human tissues by immunostaining with a MRFAP1-specific antibody revealed it was detectable in only a small number of tissues, in particular testis and brain. Strikingly, analysis of the seminiferous tubules of the testis showed highest nuclear staining in the spermatogonia and much weaker staining in the spermatocytes and spermatids. MRGBP was inversely correlated with MRFAP1 expression in these cell types, consistent with an exchange of MORF4L1 interaction partners as cells progress through meiosis in the testis. These data highlight an important new arm of the NEDD8-cullin pathway.

Introduction

Quantitative proteomic analysis has become the gold standard in recent years for unbiased analysis of cellular responses to drug treatment and the analysis of protein-protein interactions. Stable isotope labeling with amino acids in cell culture (SILAC) is one of the most accurate techniques for performing mass spectrometry based quantitative proteomics experiments (1). SILAC has been used to study a wide range of cellular protein responses, including the reliable detection of specific protein interaction partners, subcellular protein localization, and changes in protein levels resulting from viral infection, drug treatments and stress responses (2). Pulsed incorporation of amino acids containing stable isotopes was also used to measure protein turnover in nucleoli (3). Recently, detailed proteome-wide studies have used pulsed SILAC to calculate the synthesis and degradation rates of human and mouse proteins, which gives insight into protein regulation and dynamics (4, 5). In both these studies a subset of proteins were identified that have short half-lives (<3 h). Amongst this group are two known interaction partners, i.e., a chromatin regulatory protein called Mortality factor 4-like protein 1 (MORF4L1 or MRG15) and MORF4 family-associated protein 1 (MRFAP1).

3

Protein turnover plays an essential role in regulating cellular proliferation and differentiation. The ubiquitination of protein substrates mediates a large proportion of protein degradation within the cell. There are more than 600 E3 ubiquitin ligases encoded by the human genome, and of these the Cullin-based E3 ligase complexes are the most numerous and complex. The activity of Cullin E3 ligase complexes is controlled in part by their post-translational modification by the ubiquitin-like peptide NEDD8 (6, 7). NEDDylation is perfomed in an analgous way to ubiquitination, with NEDD8 initially binding an E1 enzyme complex (APP-BP1/Uba3) (8), followed by two possible E2 enzymes for conjugation to substrates (8, 9). Several enzymes are able to catalyse deneddylation, at least *in vitro*, with the most well studied being the COP9 signalosome (10).

Previous studies have shown that NEDD8 conjugation to Cullins increases their ubiquitination activity and thus the degradation rate for their substrate proteins (11). A specific inhibitor of the NEDD8 E1 enzyme complex has been identified, called MLN4924 (12). MLN4924 is currently in clinical trials as an anti-cancer agent due to its ability to trigger cellular sensence, which is thought to occur after uncontrolled DNA re-replication in S-phase (12, 13). MLN4924 rapidly blocks NEDDylation of substrate proteins, including the Cullins. A recent study has reported a large-scale proteomic and transcriptomic analysis of genes whose expression is altered upon blocking NEDD8 conjugation with MLN4924 in A375 human melanoma cells (14). This study identified 38 proteins as crucial to the cytotoxicity of MLN4924 in pathways such as cell cycle regulation, DNA repair, and ubiquitination (14).

The human NuA4 histone acetyltransferase complex is highly conserved from yeast to humans and is critical for the acetylation of histone H4 in order to regulate chromatin activity (15). Two conserved components of the NuA4 complex are MORF4L1 and MRG-binding protein (MRGBP) (15). MORF4L1 contains two domains separated by a linker region, the first being an N-terminal chromo domain that has been shown to have affinity for di- or tri-methylated histone H3 on K36 (16, 17). The second domain is the C-terminal MRG domain (MORF4-related gene domain), which has been shown to interact with MRGBP and MRFAP1 (18-20). The interaction of MORFL41 with the MRGBP protein is thought to recruit the NuA4 complex to chromatin via its chromo domain (15). The exact function of the interaction between MORF4L1 and MRFAP1 is unknown (21). However, we note that these interacting proteins were amongst the most rapidly turned over proteins identified in mammalian cells in the recent pulse-SILAC studies (4, 5).

In the present study, we have taken advantage of the specificty of the NEDD8 inihibitor MLN4924, combined with SILAC-based quantitative mass spectrometry methods to charcterize proteins downstream of the NEDD8 pathway. Here, we report that MRFAP1, a component of the MORF4L1 complex, was stabilized dramatically by MLN4924 treatment. We present evidence based upon both protein-protein interaction studies and analysis of expression in human tissues suggesting a model in which MRFAP1 competes with MRGBP for binding to MORF4L1, thereby regulating MORF4L1 function in chromatin modification. Furthermore, examination of the human tissue expression of MRFAP1 showed it may play a critical role in spermatogenesis, possibly by regulating the hyperacetylation of chromatin on histone H4.

4

Experimental Procedures

Materials –U2OS, U138MG, Tera-1 and HaCaT cells were purchased from the American Type Culture Collection (ATCC, Rockville, MD). Dulbecco's Modified Eagle Medium (DMEM), Minimal Essential medium (MEM), McCoy's 5a medium, fetal calf serum, antibiotics, NuPage gels, LDS sample buffer, MES SDS-PAGE running buffer, Nitrocellulose iBlot stacks, SYPRO Ruby, Alexa Fluor 680-conjugated secondary antibodies, and CBQCA assay kit were obtained from Life Technologies (Carlsbad, CA). IrDye 800-conjugated secondary antibodies were obtained from Rockland Immunochemicals (Gilbertsville, PA). Histo-Clear was from National Diagnostics (Atlanta, GA). Antigen unmasking solution (citric acid based) was from Vector Laboratories (Burlingame, CA). HRP-conjugated secondary antibodies were from Cell Signaling Technology (Danvers, MA). Bicinchoninic acid (BCA) assay reagents, Coomassie Plus (Bradford) reagent, Subcellular Protein Fractionation Kit, Detergent Removal Plates, 16% Methanol-Free Paraformaldehyde and Triscarboxyethylphosphine (TCEP) (Bond-breaker neutral pH solution) was from Pierce. Trypsin Gold was from Promega. Sep-Pak tC18 96-well μ-elution plates were from Waters. The Pepmap C18 columns and trapping cartridges were from Dionex. Complete protease inhibitor cocktail tablets and PhosStop phosphatase inhibitor tablets were from Roche. All other materials were obtained from Sigma.

Construction of LAP1-MRFAP1 Constructs and Cell Lines – All MRFAP1 constructs were generated by gene synthesis and cloned into the pgLAP1 vector (protein sequences are provided in Supplementary Figure 3) using Gateway cloning (Life Technologies) as described previously (22).

Cell culture –Briefly, U2OS cells were grown in DMEM supplemented with 10% FCS, 2 mM L-glutamine, 100 U/l penicillin and 100 μg/l streptomycin at 37°C in 10% CO_2, and passaged at ~80% confluence. U2OS cells expressing LAP1-tagged proteins were grown in the same media as U2OS but with the addition of 150 μg/ml Hygromycin B and 15 μg/ml Blasticidine-HCl. HaCaT cells were cultured in DMEM supplemented with 10% FCS, 100 U/l penicillin and 100 μg/l streptomycin at 37°C in 10% CO_2, and passaged at ~80% confluence. Tera-1 cells were cultured in McCoy's 5a medium supplemented with 20% FCS, 100 U/l penicillin and 100 μg/l streptomycin at 37°C in 10% CO_2, and passaged at ~80% confluence. U138MG cells were cultured in MEM supplemented with 10% FCS, 100 U/l penicillin and 100 μg/l streptomycin at 37°C in 10% CO_2, and passaged at ~80% confluence. For SILAC labeling of U2OS cells arginine and lysine free DMEM was used and supplemented with stable isotope labeled arginine and lysine in addition to dialyzed FCS as described previously (23).

Sub-cellular fractionation of U2OS Cells – For the initial SILAC screen U2OS cells were treated with either DMSO or MLN4924, combined in a 1:1 ratio of cells and fractionated using differential centrifugation and sucrose cushions as described previously to obtain crude cytoplasmic, nucleoplasmic and nucleolar fractions (24). These three fractions were then chloroform-methanol precipitated (25) and

5

further separated by molecular weight using denaturing size exclusion chromatography prior to digestion and LC-MS/MS analysis.

The Pierce Subcellular Protein Fractionation Kit was used to fractionate U2OS cells according to the manufacturer's instructions. Each fraction was chloroform-methanol precipitated prior to analysis by SDS-PAGE and immunoblotting.

SDS-PAGE and Immunoblotting– Equal amounts of protein were loaded for SDS-PAGE of each sample with 10 μg per lane, except for immunoprecipitation eluates where 10% of the elution volume was loaded. SDS-PAGE was performed using on 4-12 % (wt/vol) Bis-Tris NuPage gels using MES running buffer according to manufacturer's instructions but with the addition of 25 mM TCEP, in the LDS sample buffer. Equal amounts of protein were loaded with a maximum of 10 μg per lane. SYPRO Ruby staining was performed as per manufacturer's instructions (Invitrogen). For mass spectrometric identification SYPRO Ruby staining was performed as per manufacturer's instructions. For western blotting separated proteins were electrophoretically transferred to an iBlot nitrocellulose membrane, blocked with 3% non-fat skim milk in 0.1% Tween20 in TBS (TBST) and incubated with primary antibody in 5% BSA in TBST overnight at 4°C. After incubation, membranes were washed three times in TBST and incubated with HRP-labeled or Alexa fluor 680/IrDye 800 labeled secondary antibodies in 3% non-fat skim milk in TBST. Proteins were visualized using Immobillon chemiluminescent substrate (Millipore) and imaged with a cooled CCD camera (Fuji) for HRP-labeled secondary antibodies or a Licor Odyssey imager for Alexa fluor 680/IrDye 800 labeled secondary antibodies.

Denaturing Gel Filtration Chromatography, Trypsin Digestion and Peptide Clean-up –Using a Dionex Ultimate 3000 HPLC system, fractions resuspended in 4% SDS, 100 mM NaCl, 25 mM TCEP, 50 mM N-ethylmaleimide, 10 mM Na PO_4 pH 6.0 were heated to 65°C for 10 min, then filtered through a 0.45 μm filter. Samples were injected (20 μl per injection – 100 μg protein) onto a mAbPacSEC column (Dionex) equilibrated with 0.2% SDS, 100 mM NaCl, 10 mM Na PO_4 pH 6.0. The flow rate was 0.2 ml min^{-1} and 16 × 100 μl fractions were collected using a low protein binding 96-deep well plate (Eppendorf). Triethylamine bicarbonate (TEAB, 1 M pH 8.0) was added to each fraction to adjust the pH to 8.0, and trypsin diluted in 0.1 M TEAB was added at a ratio of 1:50 with incubation for 18 h at 37°C. SDS was removed from each fraction using detergent removal resin in 96-well plates as described previously (26). For peptide desalting trifluoroacetic acid was added to 1% (vol/vol) final concentration and peptides were purified using a Sep-Pak tC18 96-well μ-elution plate. Peptides were eluted in 200 μl of 50 % (vol/vol) acetonitrile and speedivaced to dryness prior to resuspension in 5 % (vol/vol) formic acid. Peptide concentrations were determined using the CBQCA assay after 25-fold dilution of peptide samples in 0.1 M borate buffer pH 9.3.

LC-MS/MS and Maxquant Analysis – Using a Dionex Ultimate 3000 nanoHPLC system, 1 μg of peptides in 5 % (vol/vol) formic acid were injected onto an Acclaim PepMap C18 nano-trap column (Dionex). After washing with 2 % (vol/vol) acetonitrile 0.1 % (vol/vol) formic acid peptides were resolved on a 150 mm × 75 μm Acclaim PepMap C18 reverse phase analytical column over a 100 min organic gradient with a flow

6

rate of 300 nl min^{-1}. Peptides were ionized by nano-electrospray ionization at 1.2 kV using a fused silica emitter with an internal diameter of 5 μm (New Objective). Tandem mass spectrometry analysis was carried out on a LTQ-Velos Orbitrap mass spectrometer Thermo Scientific. The data dependent acquisition method used was the FT10 protocol as described previously (27). Data were processed, searched and quantified using the Maxquant software package version 1.2.0.18 as described previously (28), using the default settings and employing the Human Uniprot database (06/07/11) containing 109824 entries. The settings used for the Maxquant analysis were: 2 failed cleavages were allowed; fixed modification was N-ethylmaleimide on cysteine; enzymes were Trypsin (K/R not before P); Variable modifications included in the analysis were methionine oxidation, deamidation of glutamine or asparagine, N-terminal pyro-glutamic acid formation, protein N-terminal acetylation. A mass tolerance of 7 ppm was used for precursor ions and a tolerance of 0.5 Da was used for fragment ions. Using the default Maxquant settings a maximum false positive rate of 1 % was allowed for both peptide and protein identification. This cut-off was used for accepting individual spectra as well as whole proteins in the Maxquant output. This threshold has previously been shown to be a rigorous method for identifying true positive matches (28). All replicates indicated are biological replicates. Protein quantitation data was always derived from a minimum of two or more peptides per protein.

GFP-IP from SILAC labeled U2OS Cells – Cells for each condition were harvested separately by trypsinization, washed in PBS and lysed in IP buffer (1% NP-40, 50 mM Tris-Cl pH 7.4, 10% glycerol, 150 mM NaCl, Roche Complete Protease Inhibitor Cocktail, PhosStop, 50 mM N-ethylmaleimide). The lysate was centrifuged for 10 min at 17,000 g at 4°C. Equal protein amounts of each sample were then incubated with GFP-trap agarose beads from ChromoTek (Martinsried, Germany) which have been washed once in IP buffer (40 μl of 50% GFP-trap bead slurry per IP) and were incubated for 2 h at 4°C. Beads were then washed three times with IP buffer by centrifugation at 2000 g for 2 min at 4°C. SILAC mixing was performed in the first wash. Beads were resuspended in 200 μl PBS and transferred to a spin column (Pierce), and centrifuged dry at 500 g for 1 min. LDS sample buffer which has been pre-heated to 65°C was then added and incubated at 65°C for 5 min. The eluate was collected by centrifugation at 500 g for 1 min at room temperature.

Immunofluorescence Microscopy – Cells were cultured on glass coverslips as described above. All subsequent steps are at 25°C. Cells were then fixed with 3% paraformaldehyde in PBS. Fixed cells were washed with PBS, and free aldehyde groups were quenched with 50 mM glycine in PBS. The cells were then permeabilized using 1% Triton X-100 for 10 min followed by washing in PBS. Coverslips were processed for immunolabeling by blocking with 5% BSA in TBST. Primary antibodies were incubated on coverslips for 1 h in 5% BSA in TBST. Coverslips were washed by dipping 10 times into 500 mL PBS. Primary antibodies were detected with Alexa Fluor 488 or Alex Fluor 594 conjugated secondary antibodies which were incubated on coverslips for 30 min in 5% BSA in TBST.

For paraffin-embedded paraformaldehyde fixed mouse tissue sections (7 μm thick), de-parafinization was performed using Histo-Clear according to manufacturer's instructions. Citrate based unmasking solution

7

was used for antigen retrieval according to manufacturer's instructions. Cells were permeabilized using 1% Triton X-100 for 15 min followed by washing in PBS. Four 15 min incubations with 1% sodium borohydride were used for autofluorescence reduction. Tissues were processed for immunolabeling by blocking with 5% donkey serum in PBS with 0.3% Triton X-100. Primary antibodies were incubated overnight in 5% donkey serum in PBS with 0.3% Triton X-100 at 4°C. Primary antibodies were detected with Alexa Fluor 488 or Alex Fluor 594 conjugated secondary antibodies which were incubated for 1 h in 5% donkey serum in PBS with 0.3% Triton X-100 at 25°C in the dark. Optical sections were analyzed by confocal microscopy on a Leica SP2 AOBS inverted microscope. Images were generated by the maximum projection of a z-stack taken from the top to the bottom of the cell monolayer. Contrast was adjusted for all images with the same settings.

Results

Identification of Proteins Downstream of NEDD8-Cullin Pathway

Using a high specificity inhibitor of the NEDD8 E1 enzyme (MLN4924) we have interrogated the NEDD8 pathway in U2OS cells. Given that NEDD8 conjugation to Cullins is known to regulate their E3 ubiquitin ligase activity, we chose to identify those proteins whose expression increased after NEDD8 inhibition and therefore may be regulated downstream of the Cullins. We have used SILAC-based quantitative proteomics to perform a differential screen comparing the relative abundance of proteins in either control, DMSO treated U2OS cells, or in U2OS cells treated for 18 hours with 1 μM MLN4924 grown in media containing either light (R0K0) or heavy (R10K8) stable isotope-labeled amino acids, respectively. Protein extracts from both the control and MLN4924-treated cells were mixed, fractionated, digested with trypsin into peptides and analyzed by mass spectrometry on a LTQ Velos as described in the methods section. Peptides were identified and SILAC ratios quantitated using MaxQuant, which showed that out of >2,500 protein groups detected, 32 protein groups increase more than 2-fold in relative abundance after 18 h of MLN4924 treatment (Figure 1a and Supplementary Table 1). Amongst these up-regulated proteins, MRFAP1 and MORF4L1 stood out from the top six most up-regulated proteins as they had been previously shown to be interaction partners (18), and to have fast turnover rates (4, 5). These two proteins were therefore selected for further analysis.

We confirmed the MS identification data using sub-cellular fractionation and protein blotting with antibodies specific for MRFAP1 and MORF4L1, which also showed that MRFAP1 and MORF4L1 are predominantly soluble nuclear proteins whose abundance increases following treatment of cells with MLN4924 (Figure 1b). To determine whether the increase in the abundance of MRFAP1 in response to NEDD8 inhibition was conserved across different cell types we also treated HaCaT (keratinocytes), U138MG (gliobastoma), and Tera-1 (pluripotent testicular teratoma) cells with MLN4924. Immunoblotting of total cell lysates from each of these cell types confirmed up-regulation of MRFAP1 levels in each case (Figure 1c). To ensure that the antibody was specifically recognizing MRFAP1 and not other proteins in the extracts we utilized siRNA knockdown of MRFAP1 in several cell lines, followed by both

immunoblotting and indirect immunofluorescence microscopy (Supplementary Figure 1). In each case a major band at ~15 kDa, the predicted size for MRFAP1, was detected that was reduced after siRNA treatment with oligonucleotides specific for MRFAP1. These data showed the antibody recognizes MRFAP1 specifically in multiple cell lines and would be useful for further analysis of the protein. To confirm the subcellular localization of MRFAP1 indirect immunofluorescence microscopy was performed on U2OS cells either with, or without MLN4924 treatment. This showed MRFAP1 to have a nucleoplasmic localization that was increased in abundance after NEDD8 inhibition (Figure 1d). A marked increase in nuclear size was also observed (Figure 1d, arrowheads) and would be consistent with DNA re-replication, which is a known consequence of MLN4924 treatment (12).

MRFAP1 is Stabilized by NEDD8 Inhibition and Co-expression of MORF4L1

To determine how MRFAP1 protein abundance was increased after NEDD8 inhibition, we tested if the degradation of the protein was altered either with, or without, overnight MLN4924 treatment. A cycloheximide time course after overnight incubation of U2OS cells with either 1 μM MLN4924, or DMSO control treatment, showed as expected an increase in MRFAP1 protein abundance upon NEDD8 inhibition as well as a decrease in the rate of MRFAP1 degradation (Figure 2a). Strikingly, analysis of DMSO treated control cells showed MRFAP1 to have a very fast turnover rate, with almost no protein detected after 2 h of cycloheximide treatment. To confirm this result we examined the turnover of LAP-1 tagged, wildtype MRFAP1 (Supplementary Figure 3a) expressed in an inducible stable U2OS cell line as described previously (22). Using an 8 hour time course of cycloheximide treatment we showed the exogenous MRFAP1 had very similar degradation kinetics to endogenous MRFAP1 (Figure 2b). To determine whether this degradation was mediated via ubiquitin conjugation, we constructed a LAP1-tagged MRFAP1 mutant that was not competent for ubiquitin conjugation (7KR), which was expressed in a second inducible stable U2OS cell line just as for the wildtype protein (Figure 2b). In the 7KR mutant all seven lysine residues in the MRFAP1 protein have been mutated to arginines (Supplementary Figure 3b), thereby preventing modification by ubiquitin, which must be linked to lysine residues. This fusion protein can however still be ubiquitinated within the LAP1-tag which contains lysine residues (22). Regardless, the MRFAP1 7KR mutant was more stable than the wild type protein (Figure 2b). To test whether it was the co-expression of MRFAP1 and MORF4L1 after MLN4924 treatment that helped stabilize each protein, we generated a third inducible stable cell line expressing each protein at close to equimolar levels. This cell line was generated using a new construct consisting of LAP1-tagged wildtype MRFAP1 followed by a picornoviral ribosome skipping sequence (29) and then MORF4L1-mcherry (Supplementary Figure 3c). The exogenous LAP1-MRFAP1 in these cells showed similar increased stability in the presence of equimolar amounts of MORFL41 to that of endogenous MRFAP1 from cells treated with MLN4924 (Figure 2b). To determine whether endogenous MRFAP1 degradation was mediated via the proteasome, we exposed U2OS cells to a cycloheximide time course with either 10 μM MG132, or DMSO control

9

treatment. This showed as expected an increase in MRFAP1 protein abundance upon proteasome inhibition as well as a decrease in the rate of MRFAP1 degradation (Figure 2c).

MRFAP1 Interacts with E3 Ubiquitin Ligases

Next we investigated which proteins may be controlling MRFAP1 and MORF4L1 turnover. To do this we constructed inducible U2OS stable cell lines that express either wildtype LAP1-MRFAP1 or wildtype LAP1-MORF4L1 and used these to perform SILAC-based quantitation of the interaction partners for each of these proteins (22). In these triple SILAC experiments we compared GFP-based immunoprecipitates from uninduced cells (light), doxycycline induced (medium), and doxycycline induced cells with simultaneous MLN4924 treatment (heavy). This experimental design allowed discrimination between strong interactors and contaminant proteins for each of the three conditions. Analysis of the LAP1-MRFAP1 immunoprecipitates revealed strong binding to previously identified interaction partners of MRFAP1, including MORF4L1 and MORF4L2, which were enriched in MLN4924 treated cells because of their increased abundance after NEDD8 inhibition (Figure 3a). A number of ubiquitination-related proteins were also identified, as well as ubiquitin itself, including the HECT-domain containing E3-ligases UBR5 (EDD) and HUWE1, Cullin-4A/B and one of its substrate binding proteins VprBP, as well as the deubiquitination enzyme OTUB1. In addition, MRFAP1 showed interactions with coronin-1c, a WD40-repeat containing protein, which has previously been associated with F-actin binding but may have other roles with regard to MRFAP1 regulation. We were unable to detect any chromatin modification/remodeling enzymes in our MRFAP1 immunoprecipitates, which may indicate that MRFAP1, which binds to MORF4L1 via its MRG domain (20), blocks the MORF4L1 interaction with these complexes. Curiously, we consistently observed increased background binding of proteins from cells treated with MLN4924 as seen in Figure 3a by the cloud of background binders offset from (0,0). This phenomenon may relate to the effect of the drug on cellular architechture/cytoskeleton.

After comparing the SILAC ratios for each of these interactors it was clear that VprBP and Cullin-4A/B only interacted strongly with MRFAP1 following MLN4924 treatment. This could be the result of an inactive cullin being unable to dissociate from its substrate due to an inability to carry out ubiquitination. To verify these data we again immunoprecipitated LAP1-MRFAP1 from extracts of cells treated with MLN4924, separated the proteins by SDS PAGE and immunoblotted with antibodies specific for Cul4b, VprBP and Cul4a. These data showed that Cul4b but not Cul4a was co-immunoprecipitated with MRFAP1 and confirmed our mass spectrometry quantitation, because the association of MRFAP1 with Cul4b was almost undetectable in untreated cells, but was clearly seen from cells treated with either MLN4924, or MG132 (Figure 3b). The interaction between MRFAP1 and VprBP was also confirmed and showed strongest binding with MLN4924 treatment and weaker binding with MG132 treatment.

Analysis of the LAP1-MORF4L1 immunoprecipitates revealed strong binding to previously identified interaction partners of MORF4L1, including MRFAP1 and MRGBP, both of which bind to MORFL4 through its MRG domain (Figure 4a). We observed strong binding to a number of other components of

10

the NuA4 histone acetylation complex in addition to MRGBP, including BRD8 and EP400. Components of other chromatin modifying complexes were also seen, including GATAD1, a component of the JARID1A histone demethylase complex and PHF12, a component of the Sin3a histone deacetylase (HDAC) complex. Weaker interaction of MORFL41 with all of the core histones was also seen in control cells, but this was decreased after MLN4924 treatment. The recently identified MORF4L1-binding, DNA damage response protein PALB2 (FANCN) was also observed in our immunoprecipitates (30, 31). These data provide an overview of the variety of MORF4L1 containing complexes within U2OS cells and demonstrate our ability to observe several low abundance protein complexes.

To further clarify the role of Cul4B in the regulation of MRFAP1 we also carried out immunoprecipitation experiments to detect LAP1-CUL4B interacting partner proteins in extracts from cells either with, or without, MLN4924 treatment (Figure 4b). These data demonstrated how effective NEDD8 de-conjugation was for Cul4b after MLN4924 treatment. Thus, we can clearly see NEDD8 association with Cul4b in untreated cells, as well as association with components of the de-neddylating COP9 signalosome, such as CSN1 (10) as indicated by the high positive M/L ratio observed for these proteins. However, these interactions are largely abolished in MLN4924 treated cells as indicated by the negative H/L ratio observed for these proteins. We also observed interaction of Cul4b with the substrate binding protein VprBP, which we also observed interacting with MRFAP1. However, MRFAP1 itself was not observed. MORF4L1 was observed interacting with Cul4b in MLN4924 treated cells, again indicating that Cul4b has an increased affinity for the MRFAP1-MORF4L1 complex after NEDD8 inhibition. TMEM43, which is a component of the inner nuclear membrane (32), showed a strong interaction which may be related to the nuclear localization of Cul4b in U2OS cells (Human Protein Atlas, www.proteinatlas.org (33)). RBX1 and DDB1 are previously known components of Cul4b containing protein complexes (34).

MRFAP1 is inversely correlated with MRGBP Expression in Testis

Next we used a complementary microscopy-based strategy to investigate the expression pattern and associations of the interacting proteins identified above. Using the antibody specific for MRFAP1, which we previously validated by siRNA knockdown in a variety of cell types, we examined the tissue microarrays developed for the Human Protein Atlas project (www.proteinatlas.org (33)) to determine the expression pattern and subcellular localization of MRFAP1 in normal and cancerous human tissue (Supplementary Tables 2 and 3). This analysis revealed that MRFAP1 had moderate nuclear expression in the spermatogonia of the testis, strong nuclear or cytoplasmic expression in ciliated epithelia and strong cytoplasmic expression in neurons (Figure 5a, nuclear staining indicated by arrow heads), while most other tissues had weak or negative staining (Supplementary Table 2). The expression of MRFAP1 in spermatogonia may indicate the protein plays some role in spermatogenesis and the initial stages of meiosis (Supplementary Figure 4).

To determine how the expression patterns of MORFL41, MRGBP and BRD8 compared to that of MRFAP1, we examined the Human Protein Atlas testis tissue staining data (www.proteinatlas.org (33)),

11

which utilized antibodies recognizing each of these proteins. This showed that MORF4L1 was detected at all cell stages of spermatogenesis, but that MRGBP and BRD8, two components of the NuA4 histone acetyltransferase complex, were highly enriched in spermatocytes and spermatids (Figure 5b, www.proteinatlas.org (33), also see Supplementary Figure 4 for a description of spermatogenesis in the testis). Strikingly, when MRGBP expression in all tissues was examined, testis showed the strongest expression and most other tissues were negative (www.proteinatlas.org (33)). In cancer tissues MRFAP1 showed a very similar expression pattern to normal tissues, with highest expression in glioblastoma and testicular cancer (Supplementary Table 3). However, the MRGBP protein was largely undetectable in testicular cancer, in stark contrast to its expression in normal tissues. To confirm the subcellular localization of MRFAP1 in normal testis we performed indirect immunofluorescence confocal microscopy on mouse testis sections (Figure 5c). This analysis confirmed the nuclear localization of MRFAP1 in spermatogonia (Figure 5c, white arrowheads). We conclude that in human seminiferous tubules of the testis the MORF4L1 protein is expressed in all cells, but with a largely mutually exclusive co-expression of the alternate interacting proteins MRFAP1 and MRGBP.

Discussion

In the present study we have used SILAC-based quantitative mass spectrometry to characterize several nuclear proteins regulated by the NEDD8 pathway. We have identified MRFAP1 and MORF4L1 as being up-regulated in U2OS cells in response to inhibition of NEDD8 conjugation by treatment of cells with the inhibitor MLN4924. The up-regulation of MRFAP1 is mediated by an increase in the stability of the MRFAP1 protein after MLN4924 treatment. This stabilization could be enhanced due to the formation of a stable complex between MRFAP1 and MORF4L1. We further interrogated the protein-protein interaction network formed by these proteins and identified the E3 ubiquitin ligase Cul4b complex as binding to MRFAP1. This provides a putative mechanism to link the NEDD8-regulated Cul4b protein and stabilization of MRFAP1 (Figure 6). We also saw that MRFAP1 and MRGBP could not be co-immunoprecipitated and therefore may bind in a mutually exclusive manner to MORFL41. We infer that MRFAP1 could therefore act as a regulator of MORF4L1 activity by changing its binding partners.

The proteomic analysis we present here highlighted only a subset of proteins whose expression was up-regulated by 18 hours of MLN4924 treatment. The short period of NEDD8-conjugation inhibition used in this study may favor the detection of proteins which are rapidly degraded, downstream of the NEDD8-cullin E3 ubiquitin ligase pathways. A recent study which examined in detail the transcriptional and proteome response to MLN4924 treatment in human A375 melanoma cells reported a larger number of proteins whose abundance was altered (14). This may reflect differences in cell types studied and/or experimental conditions used. Regardless, Liao *et al.* also observe the increased abundance of MRFAP1 and MORF4L1 in human A375 melanoma cells after MLN4924 treatment, which adds further evidence to the universal response of cells to up-regulate these proteins after NEDD8-conjugation inhibition.

Analysis of the human tissue expression pattern of MRFAP1 showed it to be expressed in only a few cell types, including spermatogonia, ciliated epithelial cells and neurons. Closer examination of the testis expression pattern for MRFAP1 and MRGBP indicated an anti-correlated pattern, suggesting that recruitment of NuA4 histone acetyltransferase activity to chromatin via MORFL41 might be important for later stages of spermatogenesis. This is because only the cells in later stages of spermatogenesis showed co-expression of MRGBP and MORF4L1 but not MRFAP1. The MORF4L1-MRGBP modification complex could be inhibited in spermatogonia due to high MRFAP1 expression, which we suggest competes with MRGBP for binding to MORF4L1. We propose that this may block the hyperacetylation pathway in spermatogonia in order to maintain a germ stem cell population.

Previous studies have shown in a number of animals, including rats and mice, that hyperacetylation of histone H4 is critical for spermatogenesis (35, 36). These studies showed that hyperacetylation of histone H4 leads to chromatin de-condensation, which is thought to allow for histone replacement by protamines and thereby facilitate the extensive chromatin compaction needed in the small sperm nucleus (Supplementary Figure 4). We propose that the NuA4 histone acetyltransferase complex, which contains MRGBP and BRD8, plays a critical role in spermatogenesis by mediating the hyperacetylation of histone H4. One of the other MORF4L1 interacting proteins we observed was EP400, which as part of the human NuA4 complex may also play a role in the exchange of histone H2A for histone H2A.Z during spermatogenesis (37).

The MRFAP1 protein is highly conserved and only present in mammals, consistent with it playing a specific role in the regulation of MORF4L1 protein complexes (Supplementary Figure 2). MRFAP1 may thus be expressed in spermatogonia to maintain normal levels of histone modification by negatively regulating recruitment of the NuA4 complex to chromatin (Figure 6).

Analysis of the MRFAP1 domain structure shows that it is a relatively simple, modular protein, with an N-terminal MRG-binding domain followed by a flexible linker region containing a number of glycine residues and a C-terminal coiled coil region that could mediate homodimerization of the MRFAP1 protein (38-40). The dimerization capability of MRFAP1 could reflect the fact that the MRG domain of MORF4L1 is a dimer, the structure of which has been solved by X-ray crystallography (20). We propose that a homodimer of MRFAP1 may bind the homodimer of MORF4L1, forming a high affinity interaction between the two dimers. The abundance of the MORF4L1-MRFAP1 complex, compared with the MORF4L1-MRGBP complex, would then be mediated, at least in part, by the probability of an encounter between each of these proteins, and therefore is related to the abundance and localization of each protein (41).

Our studies here using quantitative proteomics analyses have revealed new evidence for the functional role of NEDD8 modification in controlling gene expression during cell differentiation in mammals. This has opened up new avenues to investigate mechanisms regulating histone acetylation and its link with spermatogenesis. In view of the tissue specificity of MRFAP1 and MRGBP expression, it is possible that these proteins regulate the hyperacetylation of histone H4 during spermatogensis via a pathway dependent upon binding stoichiometry. In the context of cancer, this pathway may be involved by subtly

altering the histone modifications of chromatin, thereby altering gene expression to favor cancer cell proliferation. Our data provide evidence for a combinatorial mechanism affecting cell-specific regulation of chromatin modification that involves changing the balance between MRFAP1-MORF4L1-MRGBP interactions. In future, it will be of interest to characterize further the impact of this pathway in disease states, such as cancer, that are influenced by alterations in histone acetylation and related modifications.

FIGURE LEGENDS

Figure 1. MRFAP1 and MORF4L1 are up-regulated in response to NEDD8 inhibition. (**a**) SILAC analysis of U2OS cells following NEDD8 inhibition. The abundance of ~2,500 proteins is indicated on the y-axis using a $\log_2$ scale. The abundance of each protein indicated by the position of the dot on the y-axis was determined by summing up all individual light and heavy peptide intensities detected for each protein. The relative fold decrease or increase is shown using the $\log_2$ ratio (heavy/light) on the x-axis, with 1 μM MLN4924 treatment for 18 h (heavy) over DMSO only (light) (n=2). (**b**) Immunoblotting of subcellular fractionation from U2OS cells treated with 1 μM MLN4924 treatment for 18 h or DMSO only, (n=3). (**c**) Immunoblotting of total cell lysates from the indicated cell types treated with 1 μM MLN4924 treatment for 18 h or DMSO only, (n=2). (**d**) Immunofluorescence microscopy of endogenous MRFAP1 in U2OS cells treated with 1 μM MLN4924 treatment for 18 h or DMSO only, white arrowheads indicate change in nuclear size after MLN4924 treatment (n=3). Scale bar indicates 10 μm.

Figure 2. MRFAP1 is stabilized by NEDD8 inhibition. (**a**) Immunoblotting of total cell lysates from U2OS cells treated with 1 μM MLN4924 for 18 h or DMSO only. A time course of cycloheximide treatment followed to examine protein degradation, (n=3). (**b**) Immunoblotting of total cell lysates from either LAP1-MRFAP1 WT, LAP1-MRFAP1 7KR, or LAP1-MRFAP1-P2A-MORF4L1-mCherry after a time course of cycloheximide treatment to examine protein degradation, (n=2). (**c**) Immunoblotting of total cell lysates from U2OS cells treated with 10 μM MG132 or DMSO only. A time course of cycloheximide treatment was used to examine protein degradation. MG132 and cycloheximide were added at the same time for each time point (n=3).

16

Figure 3. MRFAP1 interacts with ubiquitin E3 ligases. (**a**), SILAC GFP-IP analysis of U2OS cells stably expressing inducible LAP1-MRFAP1 WT. GFP-immunoprecipitates from un-induced cells (light), doxycycline induced (medium), and doxycycline induced cells with simultaneous MLN4924 treatment (heavy), were mixed and analyzed together by LC-MS/MS. The $\log_2$ ratio (medium/light) is indicated on the x-axis. The $\log_2$ ratio (heavy/light) is indicated on the y-axis. High ratios indicate high abundance of interaction compared to control. Proteins of interest are indicated, (n=2). (**b**), Immunoblotting of GFP-immunoprecipitated LAP1-MRFAP1. Cells were treated with 1 μM MLN4924 for 18 h or DMSO only (n = 3).

Figure 4. MRFAP1 is part of a complex protein-protein interaction network. (**a**), SILAC GFP-IP analysis of U2OS cells stably expressing inducible LAP1-MORF4L1. (**b**), SILAC GFP-IP analysis of U2OS cells stably expressing inducible LAP1-CUL4B. GFP-immunoprecipitates from un-induced cells (light), doxycycline induced (medium), and doxycycline induced cells with simultaneous MLN4924 treatment (heavy), were mixed and analyzed together by LC-MS/MS. The $\log_2$ ratio (medium/light) is indicated on the x-axis. The $\log_2$ ratio (heavy/light) is indicated on the y-axis. High ratios indicate high abundance of interaction compared to control. Proteins of interest are indicated, (n=1).

Figure 5. Human normal tissue expression pattern of MRFAP1. (**a**) Immunohistochemistry imaging of endogenous MRFAP1 in selected tissues, brown color indicates staining, (n=3). Red arrows indicate nuclear staining in spermatogonia of testis and ciliated epithelial cells of the fallopian tube. (**b**) Immunohistochemistry imaging of endogenous protein as indicated in testis tissue, brown color indicates staining, (n=3). (**c**) Immunofluorescence microscopy of endogenous MRFAP1 in murine testis tissue, (n=3) Red arrows indicate nuclear staining in spermatogonia of testis. Scale bar indicates 10 μm.

Figure 6. Model for the regulation of MRFAP1 by the NEDD8 pathway. The NuA4 histone acetyltransferase complex is recruited to chromatin via the binding of MORF4L1 to tri/di-methylated lysine 36 on histone H3. Cells treated with MLN4924 have a defect in NEDD8 conjugation, therefore Cul4b would be less active in MRFAP1 degradation. Increase in free MRFAP1 protein displaces MRGBP from MORF4L1 and creates a stable MORF4L1-MRFAP1 complex.
